Abstract

The U.S. Geological Survey annually conducts fishery surveys across Lake Superior that describe trends in fish species occurrence and relative abundance to inform fisheries management and large lake ecology. In 2023, the Lake Superior fish community was sampled with daytime bottom and surface trawls at 51 nearshore locations in June and 31 offshore locations in July. Nearshore bottom trawls collected 157,804 fish from 25 species or morphotypes. Nearshore mean biomass was 18.3 kg per ha which was the second highest biomass estimate over the survey's 46-year history. Offshore bottom trawls collected 15,458 fish from 10 species or morphotypes. Offshore mean biomass was 5.2 kg per ha, which was less than the annual average of 6.3 kg per ha. Recruitment, as measured by age-1 densities, was the highest recorded for Bloater, Cisco, and Rainbow Smelt in the nearshore and for Kiyi in the offshore survey's period-of-records. Lakewide average densities (fish per ha) of age-1 fish were 140 for Bloater, 1,019 for Cisco, 616 for Rainbow Smelt, and 54 for Kiyi, which were the highest estimates for the survey's period-of-record. Period-of-record averages for these species were 10, 67, and 9 age-1 fish per ha, respectively. Age-1 Lake Whitefish averaged 9 fish per ha which was similar to the long-term average of 8 age-1 Lake Whitefish per ha. If the future can be predicted by past large Bloater, Cisco, and Kiyi (collectively, ciscoe) year-class events, the unprecedented survival of the 2022 ciscoe year-class will influence the Lake Superior ecosystem for the next 10 to 20-years.

Introduction

The U.S. Geological Survey, Great Lakes Science Center, Lake Superior Biological Station, based in Ashland, Wisconsin conducts annual daytime lakewide fish community bottom trawl surveys in nearshore (~15-80 m depths) and offshore (~90-300 m depths) waters that describe trends in fish species occurrence and relative abundance to inform fisheries management and large lake ecology. Both surveys provide data for assessing trends in species occurrence, relative abundance, and biomass for principal fishes and estimates of survival to age-1 for Bloater, Cisco, Kiyi, Lake Whitefish, and Rainbow Smelt (scientific names are provided in Table 1). The number of age-1 fish per ha has been used historically as a measure of year-class strength to predict future populations sizes for these important species.

The nearshore bottom trawl survey has been conducted annually since 1978 in USA waters, and since 1989 in USA and Canadian waters. The offshore bottom trawl survey has been conducted annually since 2011 in USA and Canadian waters. Surface trawling has occurred annually during the nearshore and offshore surveys since 2014. In 2020 only nearshore locations in the Apostle Islands, north of Ashland, Wisconsin, (Management Unit WI-2) were sampled and in 2021 only nearshore locations in USA waters were sampled due to COVID-related travel restrictions. Surface trawling is conducted to collect larval *Coregonus* fishes as a measure of species occurrence and relative abundance in support of evaluating factors influencing survival to age-1. Larval *Coregonus* fishes have been identified using genomics since 2019. Genomic data for 2023 are not yet available. In addition to fish collections, a whole water column zooplankton tow and an electronic water column sampler that collects data on depth, temperature, beam transmission specific conductance,

dissolved oxygen, pH, chlorophyll a, and photosynthetic active radiation is deployed at each location. Data for years prior to 2023 are publicly available (U.S. Geological Survey 2022, https://doi.org/10.5066/P9XVOLR17) and 2023 data will be available in 2024.

Methods

Nearshore bottom trawl fish collections

Nearshore locations are located around the perimeter of the lake (Figure 1). Locations were established in the USA in 1978 and in Canada in 1989. Locations are sampled with only slight annual variations due to commercial fishing operations, vessel crew manning, mechanical issues, and weather. In 2023, 59 locations were sampled from June 2-26. Thirteen traditionally sampled locations were not bottom trawled in 2023 due to not having roller trawls available (Figure 1). These 13 locations are known to have rock substrates that have proven to be detrimental to chain foot rope bottom trawls. Location 193-Salt Point in Whitefish Bay was not bottom trawled due to commercial fishing nets deployed across the transect. Two Canadian locations, 417-Schrieber Channel and 451-Dog River were not sampled due to a shortage of vessel crew. At each of the other 59 locations, a single bottom trawl tow was conducted with a 12-m Yankee bottom trawl with a chain foot rope. Bottom trawls were ripped at two locations, 177-Sucker River and 459-Maple Island, so these two locations were removed from the data set. The median start and end depths for bottom trawl tows were 17 (range 8-51 m) and 54 m (range 18-140 m), respectively. The median distance trawled was 1.6 km (range 0.7-4.0 km) at a speed of ~4.0 km per h. Specific location and trawling data for each sampling location are provided in Appendix A. Bottom trawl fishing area was calculated based on a fixed trawl wing spread of 7.8 m and the

distance the trawl was on the lake bottom as determined using a trawl mensuration system (Marport.com) and the Research Vessel Kiyi's global positioning system.

Offshore bottom trawl fish collections

Offshore locations were randomly selected in 2011 and have been sampled annually thereafter, except for 2020 and 2021. In 2023, 31 locations were sampled during daylight hours from July 10-27. Five locations that are traditionally sampled were not sampled in 2023 due to a shortage of vessel crew (Figure 1). A single bottom trawl tow was conducted at each location using a 12-m Yankee bottom trawl with a chain foot rope. All tows were made on-contour for 20 minutes. Station depths ranged from 80 to 308 m. The median trawl distance was 1.4 km (range 1.3-1.4 km) at a speed of ~4.0 km per h. Specific location and trawling data for each sampling location are provided in Appendix A. Bottom trawl fishing area was calculated based on a fixed trawl wing spread of 7.8 m and the distance the trawl was on the bottom as determined using a trawl mensuration system (Marport.com) and the Research Vessel Kiyi's global positioning system.

Surface trawl fish collections

Surface trawling was conducted at all nearshore and offshore bottom trawl locations sampled in 2023 (Figure 1, Appendix A), except at locations 142-Big Bay, 187-French River, and 196-Baker's Point due to blustery winds. Fish were collected using a paired one-square-meter 500-micron mesh neuston net (model 9550, Sea-Gear Corporation, Melbourne, Florida). The bottom of the net frame was fished ~0.5 m below the lake surface for 10

minutes at ~4.0 km per h for ~0.7 km as determined from the Research Vessel Kiyi's global positioning system.

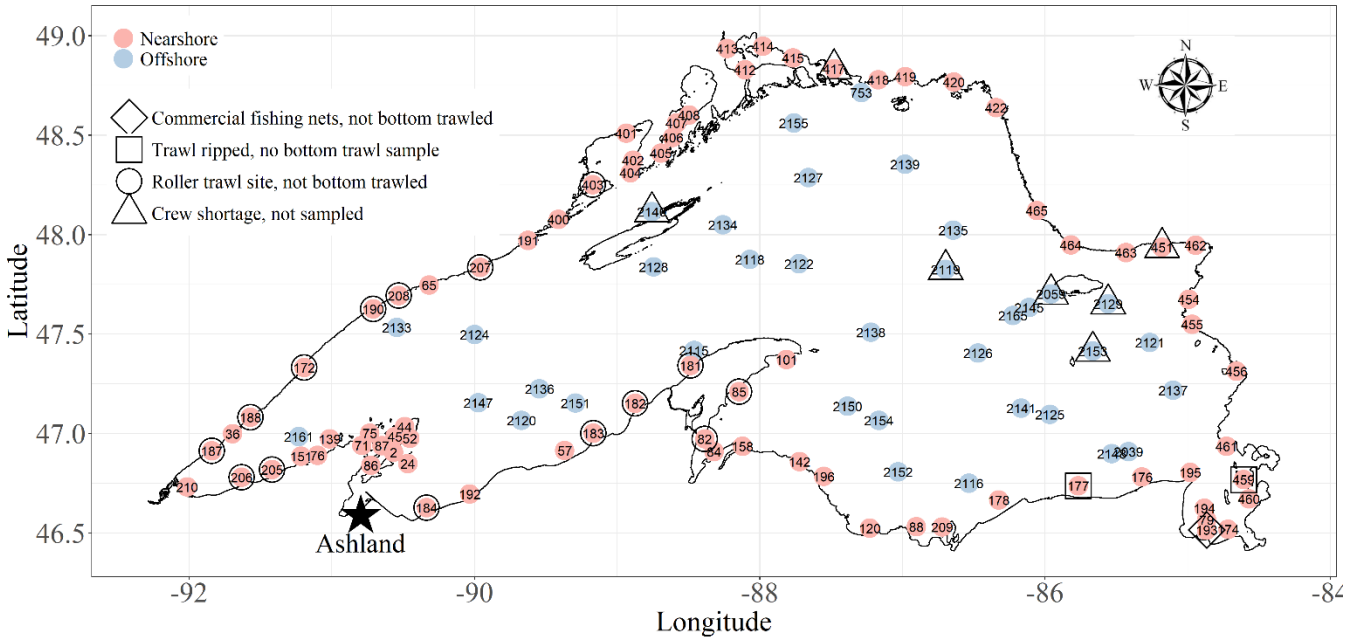

Figure 1. Location of 78 nearshore and 36 offshore sampling locations traditionally sampled with bottom and surface trawls, a whole water column zooplankton tow, and an electronic water column sampler that collects data on depth, temperature, beam transmission, specific conductance, dissolved oxygen, pH, chlorophyll a, and photosynthetic active radiation each year. Bottom trawls for benthic and demersal fish and surface trawls for larval fish occurred at 59 nearshore and 31 offshore sampling locations in 2023. Bottom trawls were not done at 13 nearshore locations due to the lack of roller trawls. Two nearshore locations were not bottom trawled due to a lack of vessel crew. Five offshore locations were not sampled for any attributes due to a lack of vessel crew. A single nearshore location was not sampled due to commercial fishing gear deployed across the transect. Bottom trawls were ripped at two locations and the partial catch was discarded. Surface trawling was not done at three locations due to high winds. Location numbers are unique identifiers that are sequentially added as new locations are sampled. Additional location and trawling data for each sampling location is provided in Appendix A.

Catch Processing

Fish collected in bottom trawls were sorted by species (also separated by morphotype for Lake Trout and hatchery vs wild for Lake Trout), counted, and weighed in aggregate to the nearest gram. In 2023, several nearshore bottom trawl catches were exceptionally large and diverse (>50 kg and >10 species) and were sub-sampled by first removing large fish (> ~175 mm) from the catch and processing them as described above. Smaller fish were then weighed in aggregate, then depending on the size of the catch, seven to 15 liters of fish were subsampled from the aggregate of small fish and a total weight was measured. This subsample was then sorted, weighed, and counted by species. From the subsample, the proportion by weight and average weight per fish for each species was calculated. These estimates were then projected to the aggregate sample of small fish to estimate the total weight and count for each species. These results were then combined with the aggregate of large fish total weights and counts. For large catches of Rainbow Smelt, the total number collected was estimated by weighing three subsamples of 50 randomly selected fish and dividing the average weight of an individual fish, as determined by the three subsamples, into the total weight. Total length was measured for a maximum of 50 individuals per species per trawl. Lengths of these individuals were extrapolated to the entire catch when more than 50 individuals were collected. Relative abundance (fish per ha) and biomass (kg per ha) were estimated by dividing sample counts and aggregate weights by the area swept by each trawl tow (ha). For annual nearshore bottom trawl collections, biomass estimates are reported for all species combined and individually for Bloater, Cisco, Lake Whitefish, and Rainbow Smelt, and combined for Sculpin species (Slimy, Spoonhead, and Deepwater Sculpin). A composite estimate is also reported for less-common species (Table 1). For

offshore bottom trawl collections, biomass estimates are reported for all species combined and individually for Deepwater Sculpin, Kiyi, and siscowet Lake Trout. Age-1 year-class strength was estimated as the mean nearshore lakewide abundance (fish per ha) of age-1 fish as determined by total length; Cisco <140 mm, Bloater <130 mm, Lake Whitefish <160 mm, and Rainbow Smelt <100 mm, and for offshore collected Kiyi <130 mm. These age-size cutoffs were based on past published age estimates, are approximate, and are known to vary among years (Dryer and Beil, 1964, 1968. Lepak et al. 2017).

Larval fish collected in surface trawls were immediately removed from the nets and identified as *Coregonus*, Deepwater Sculpin, Rainbow Smelt, or Pacific Salmon based on morphological characters (Hinrichs 1979; Auer 1982). *Coregonus* larvae were counted and stored in 20 ml polyethylene scintillation vials filled with 90% ethanol. Other larval species were noted as being present and discarded. Larval fish densities were calculated based on the width of the sampling nets and the distance towed. Data are not reported for 2020 and 2021 as fewer locations were sampled due to COVID restrictions.

Data Analysis, Visualization, and Availability and USGS Disclaimer

All data manipulations, statistical analyses, and visualizations were performed in R version 4.0.5 (R Development Core Team 2023). Data visualizations were produced using ggplot2 (Wickham 2016). Data for years prior to 2023 are publicly available (U.S. Geological Survey 2022, https://doi.org/10.5066/P9XVOLR17) and 2023 data will be available in 2024. Any use of trade, product, or firm names is for descriptive purposes only and does not imply endorsement by the U.S. Government.

Results

Nearshore Fish Collections

A total of 157,804 fish from 25 species or morphotypes were collected across 57 nearshore locations (Table 1). The number of species collected at each location ranged from 2 to 15, with a median of 9 species. Estimated fish biomass at individual locations ranged from <0.1 to 141.7 kg per ha (Figure 2). The five locations with the highest biomass in 2023 were 2-Stockton Island in the Apostle Islands (142 kg per ha), 151-Bark Point, Wisconsin west of the Apostle Islands (71 kg per ha), 101-Bete Grise on the east side of the tip of the Keweenaw Peninsula (62 kg per ha), 76-Mawikwe Point, Wisconsin, west of the Apostle Islands (51 kg per ha), and 418-Terrace Bay, Ontario, northeast of Thunder Bay, Ontario (49 kg per ha, Figure 2). Average lakewide fish biomass across all locations was 18.3 kg per ha, which was the second highest lakewide biomass estimate over the survey's 46-year history (Figure 3). Average lakewide biomass in 2023 was highest for Cisco (10.5 kg per ha), Lake Whitefish (2.4 kg per ha), Rainbow Smelt (2.4 kg per ha), and Bloater (1.1 kg per ha, Table 1), which were greater than the long-term averages for all of these species other than Bloater (long-term mean = 1.5 kg per ha, Table 2). Other species collected in nearshore bottom trawl tows in 2023 (number collected) included Ninespine Stickleback (3,564), Trout-perch (1,620), Slimy Sculpin (1,195), Pygmy Whitefish (580), Deepwater Sculpin (725), Spoonhead Sculpin (378), Kiyi (314), Longnose Sucker (96), Ruffe (55), lean Lake Trout (49), siscowet Lake Trout (46), hatchery Lake Trout (19), Round Whitefish (18), Johnny Darter (18), Burbot (16), Yellow Perch (6), unidentified *Coregonus* (6), Spottail Shiner (5), Threespine Stickleback (4), and one each of Lake Sturgeon and Logperch.

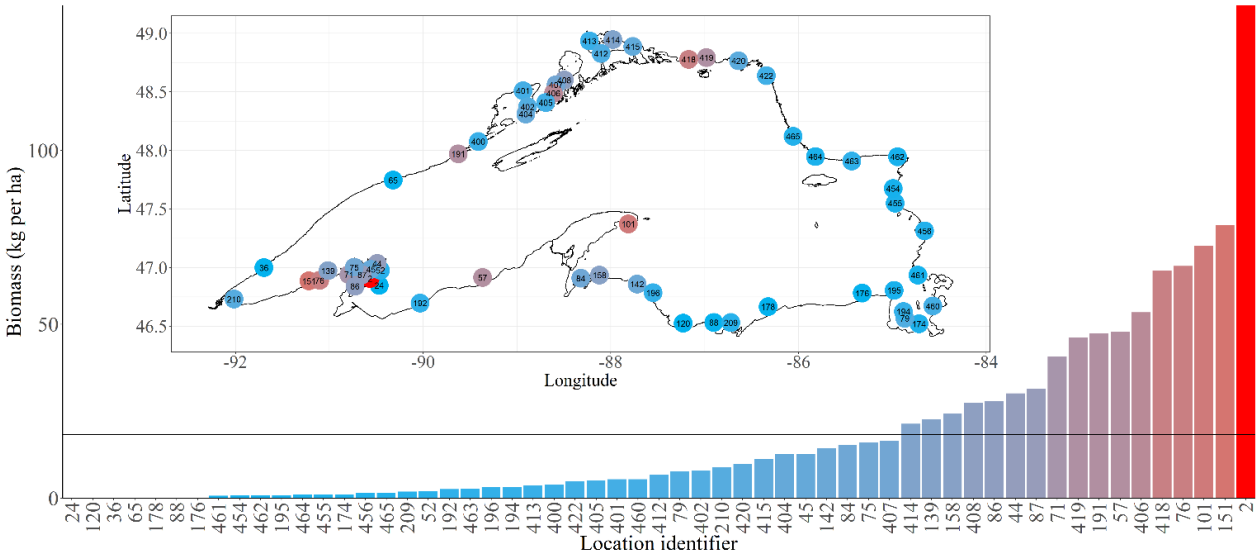

Figure 2. Estimated total fish biomass (kg per ha) at 57 nearshore bottom trawling locations in nearshore USA and Canada waters of Lake Superior in 2023. Nearshore sampling locations were 17-140 m deep. The horizontal line is the 2023 average biomass across all locations (18.3 kg per ha). The inset figure shows sampling locations colored by their estimated biomass (kg per ha) in 2023. Colors within inset map correspond to color in the histogram.

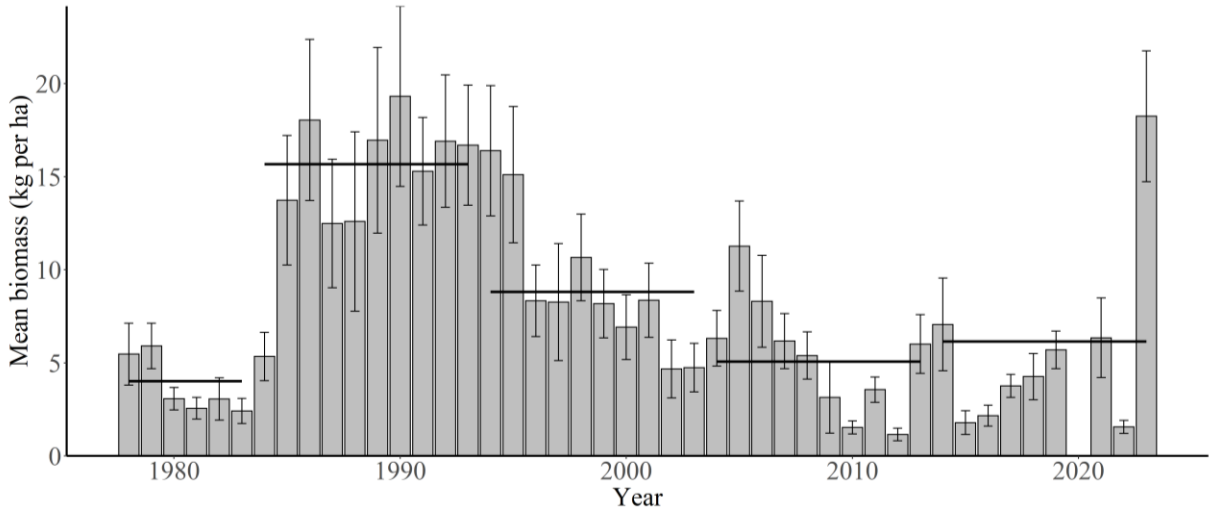

Figure 3. Annual (mean ± standard error) total fish biomass estimates for all fish species collected in bottom trawl tows from 1978-2023 in nearshore USA and Canada waters of Lake Superior. Nearshore sampling locations were 17-140 m deep. Horizontal lines are 10-year averages across different periods. In 2020 sampling occurred outside the standard sampling window and only 11 locations were sampled in the Apostle Islands, north of Ashland, Wisconsin (Figure 1), so these data were excluded. From 1978-1988 and in 2021 only USA waters were sampled. The number of locations sampled in each year is presented in Table 2.

Year-Class Strength

The number of age-1 fish per ha has been used historically as a measure of year-class strength. In 2023, age-1 Bloater were caught at 38 of 57 locations (Figure 4) and the average lakewide age-1 abundance was 140 per ha (Figure 5). Age-1 Cisco were caught at 43 of 57 locations (Figure 4) and the average lakewide age-1 abundance was 1,019 per ha (Figure 5). Age-1 Bloater and Cisco abundance estimates were the highest for the survey's 46-year period-of-record (Figure 5, Table 3). Period-of-record averages for these species were 10, 67, and 9 age-1 fish per ha, respectively. Age-1 Lake Whitefish were caught at 17 of 57 locations (Figure 4) and the average age-1 abundance was 9 per ha, which was similar to the long-

term average of eight age-1 Lake Whitefish per ha (Figure 5, Table 3). Mean age-1 Rainbow Smelt abundance was the highest for the nearshore survey's period of record, 615 per ha (Table 3). Age-1 Rainbow Smelt abundance was particularly high (>600 per ha) in northern Ontario; stations 418-Terrace Bay, Ontario (9,371 per ha), 405, 406, 407, 408-Black Bay, Ontario (999-9,363 per ha), 404-Dublin Creek in Nipigon Bay, Ontario (953 per ha), and 420-Ashburton Bay, Ontario (779 per ha), as well as stations 101-Bete Grise (1,331 per ha), 192-Black River (1,276 per ha), and 158-Huron Bay (1,171 per ha) in the USA (Figure 6).

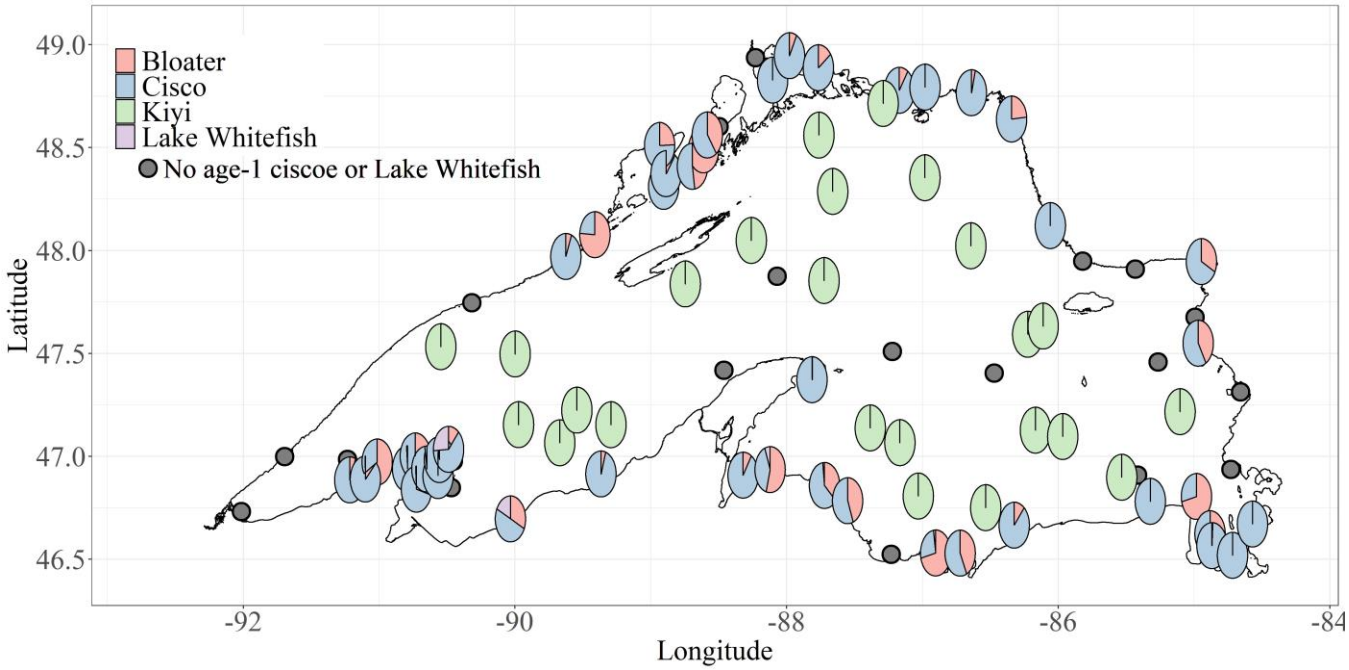

Figure 4. Proportional abundance occurrences of age-1 Bloater, Cisco, Kiyi, and Lake Whitefish collected in near- and off-shore surveys in USA and Canada waters of Lake Superior in 2023. Nearshore sampling locations were 17-140 m deep and offshore locations were 80-308 m deep. Gray solid points indicate no age-1 Bloater, Cisco, Kiyi, or Lake Whitefish were collected at that location. The location of individual stations by identification number is shown in Figure 1.

The effect of not sampling 13 traditional nearshore roller trawl locations

Thirteen traditionally sampled locations were not bottom trawled in 2023 due to not having any roller trawls available (Figure 1). The influence of not sampling these locations on lakewide total biomass and age-1 estimates for Bloater, Cisco, Lake Whitefish, and Rainbow Smelt was evaluated by excluding these locations for the nearshore survey period-of-record and comparing the annual indices with and without sampling roller trawl locations. The overall magnitude of the differences in lakewide total mean biomass and age-1 index values across all years among indices ranged from 8-13% higher estimates on average when roller trawl locations were removed from the data set (Appendix B, total biomass, 10.4%, age-1 Bloater 8.5%, age-1 Cisco 10.7%, age-1 Lake Whitefish 13%, and age-1 Rainbow Smelt 10.5%). Differences in median values across the period-of-record ranged from 7-15% (Appendix B). These results suggest that the index values estimated in 2023 were slightly higher than they would have been had the 13 roller trawl sites been sampled. These differences were not large enough however to change the general interpretation that fish population estimates in 2023 were some of the highest on record.

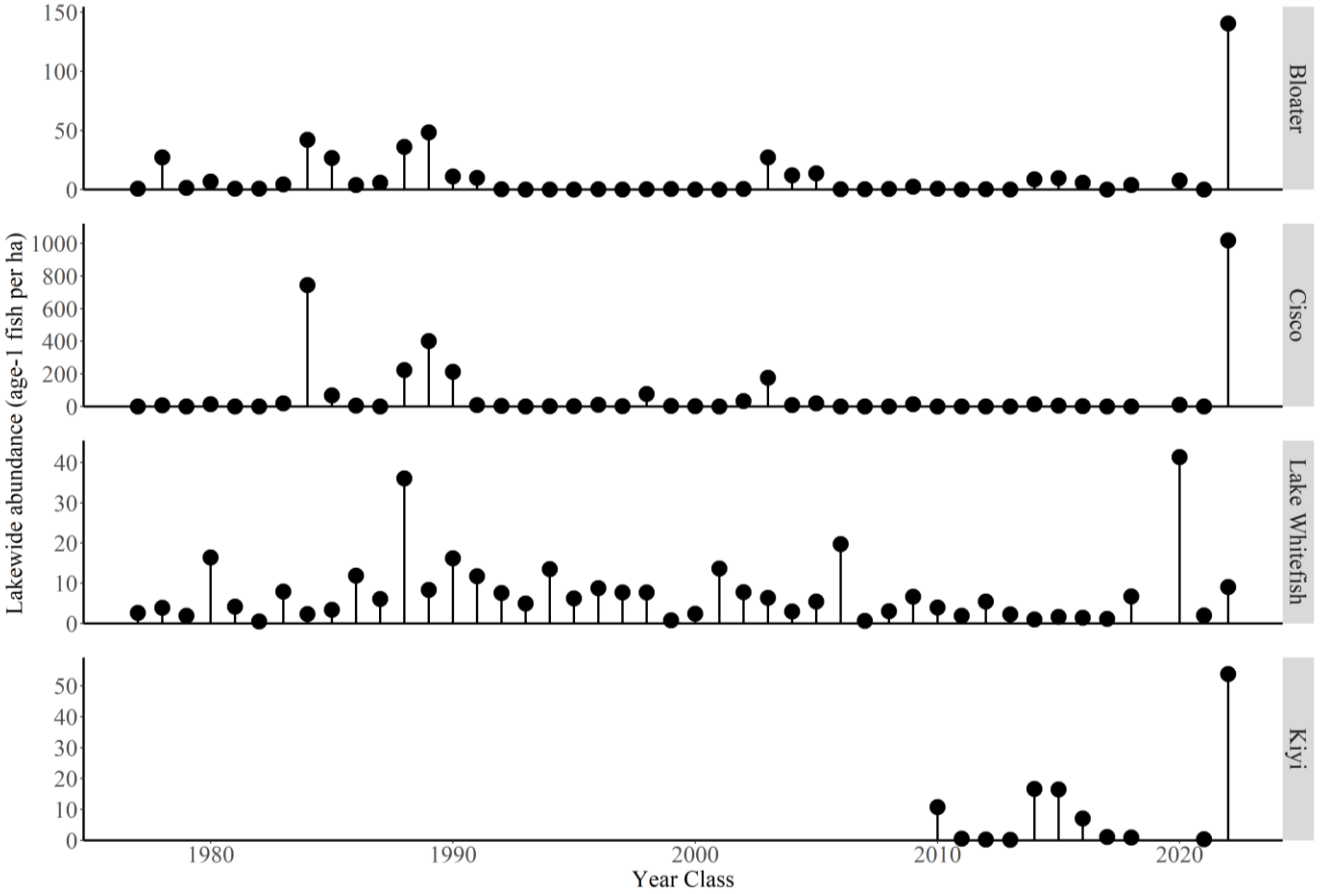

Figure 5. Annual mean age-1 nearshore Bloater, Cisco, and Lake Whitefish and offshore Kiyi abundance estimates (age-1 fish per ha) collected in bottom trawl tows from 1978-2023 in nearshore surveys and 2011-2023 in offshore surveys in USA and Canada waters of Lake Superior. Nearshore sampling locations were 17-140 m deep and offshore locations were 80-308 m deep. In 2020 sampling occurred outside the standard sampling window and only 11 locations were sampled in the Apostle Islands, north of Ashland, Wisconsin (Figure 1), so data for the 2019 year-class were excluded. From 1978-1988 and in 2021 only USA waters were sampled. The number of locations sampled in each year is presented in Table 3.

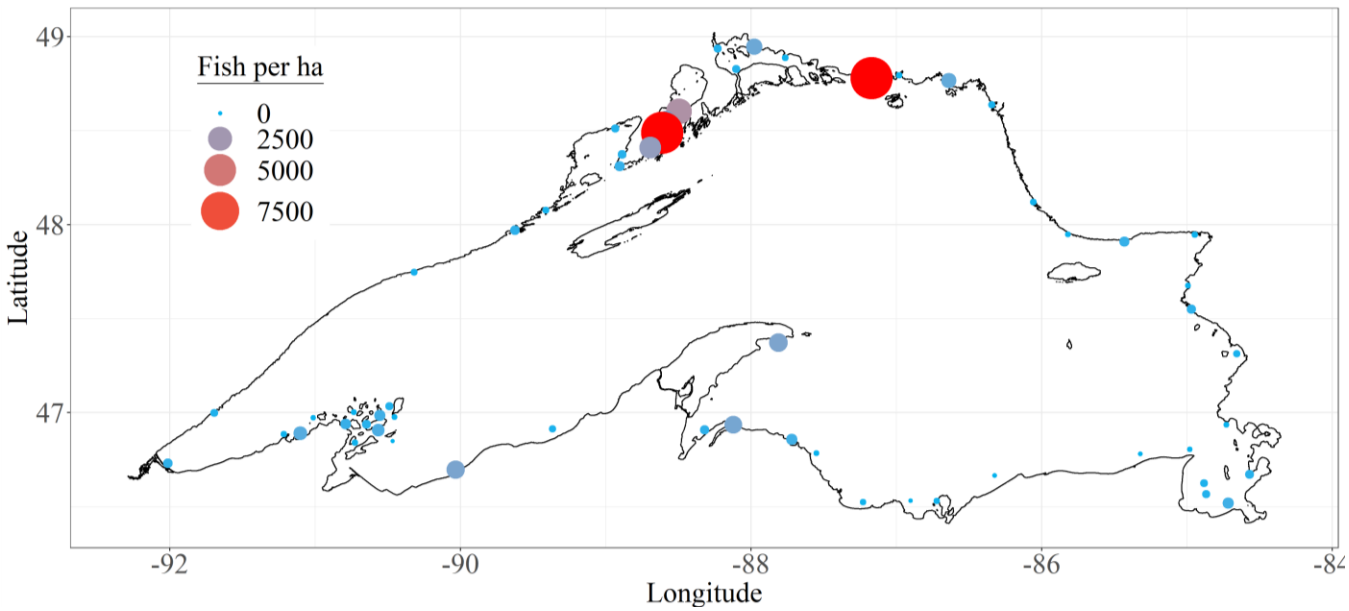

Figure 6. Rainbow Smelt abundance (fish per ha) in nearshore surveys in USA and Canada waters of Lake Superior in 2023. Nearshore sampling locations were 17-140 m deep. The location of individual stations by identification number is shown in Figure 1.

Annual Offshore Fish Collections

Thirty-one offshore locations were sampled in 2023 from which 15,458 fish from 10 species or morphotypes were collected (Table 1). Estimated fish biomass at individual locations ranged from 1.0 to 15.4 kg per ha (Figure 7). Individual locations with the highest biomass in 2023 were locations 2135, a 140 m deep location near Superior Shoal, Ontario, 2125, a 175 m deep location north of Grand Marais, Michigan, and 2116, a 165 m deep location north of Munising, Michigan (Figure 7). Offshore mean biomass was 5.2 kg per ha, which was less than the long-term (2011-2023) annual average of 6.3 kg per ha.

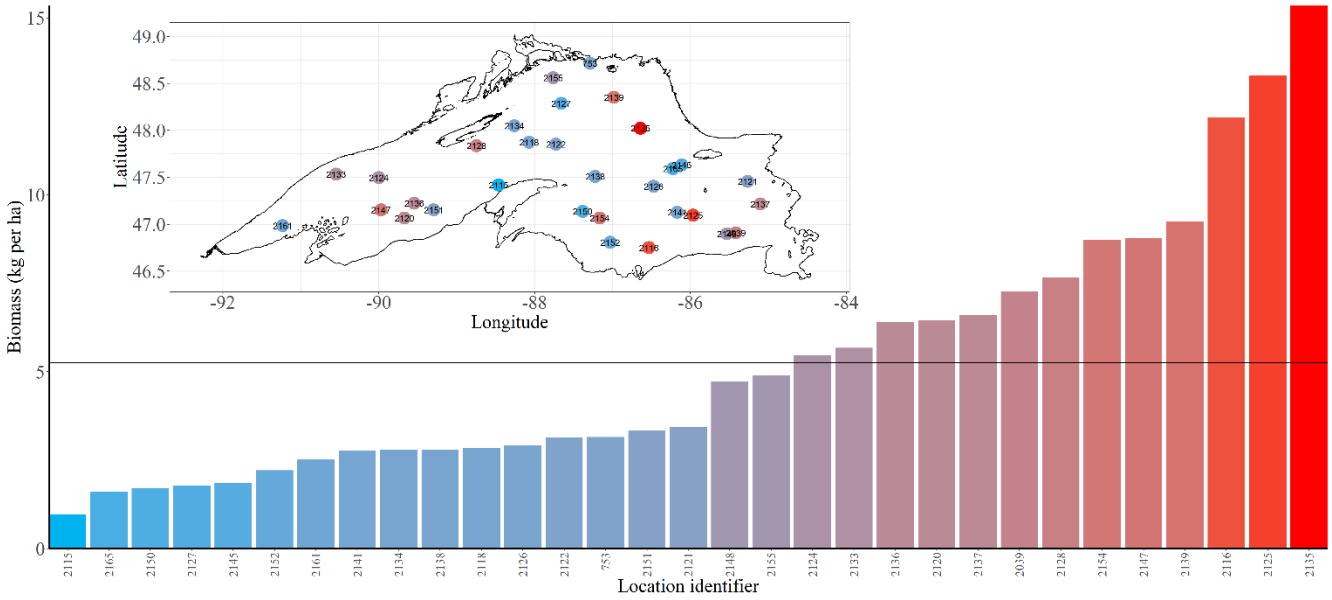

Figure 7. Estimated biomass (kg per ha) at individual offshore locations in USA and Canada waters of Lake Superior in 2023. The horizontal line is the 2023 lakewide offshore average biomass (5.2 kg per ha). The inset figure shows sampling locations colored by their estimated biomass (kg per ha) in 2023. Colors within inset map correspond to color in the histogram.

Deepwater Sculpin, Kiyi, and siscowet Lake Trout made up 99% of the total number of individuals and biomass collected in offshore waters (Table 1). Other fish collected in much lower abundances were Bloater (18 fish), Slimy Sculpin (15 fish), Spoonhead Sculpin (6 fish), Cisco (3 fish) and two fish each of Rainbow Smelt, Pygmy Whitefish, and Burbot (Table 1). Deepwater Sculpin offshore biomass averaged 1.8 kg per ha in 2023, which was similar to the long-term average of 1.9 kg per ha (Figure 8). Kiyi offshore biomass averaged 0.9 kg per ha in 2023 which was less than the long-term average of 1.3 kg per ha (Figure 8). Age-1 Kiyi abundance at offshore locations was 54 fish per ha in 2023 which was the highest estimate for the period-of-record of the survey (2011-2023, Figure 5, Table 3). The previous high abundance for age-1 Kiyi was 17 and 16 fish per ha for the 2014 and 2015 year-classes.

Siscowet Lake Trout biomass averaged 2.6 kg per ha in 2023, which was slightly less than the long-term average of 2.8 kg per ha (Figure 8).

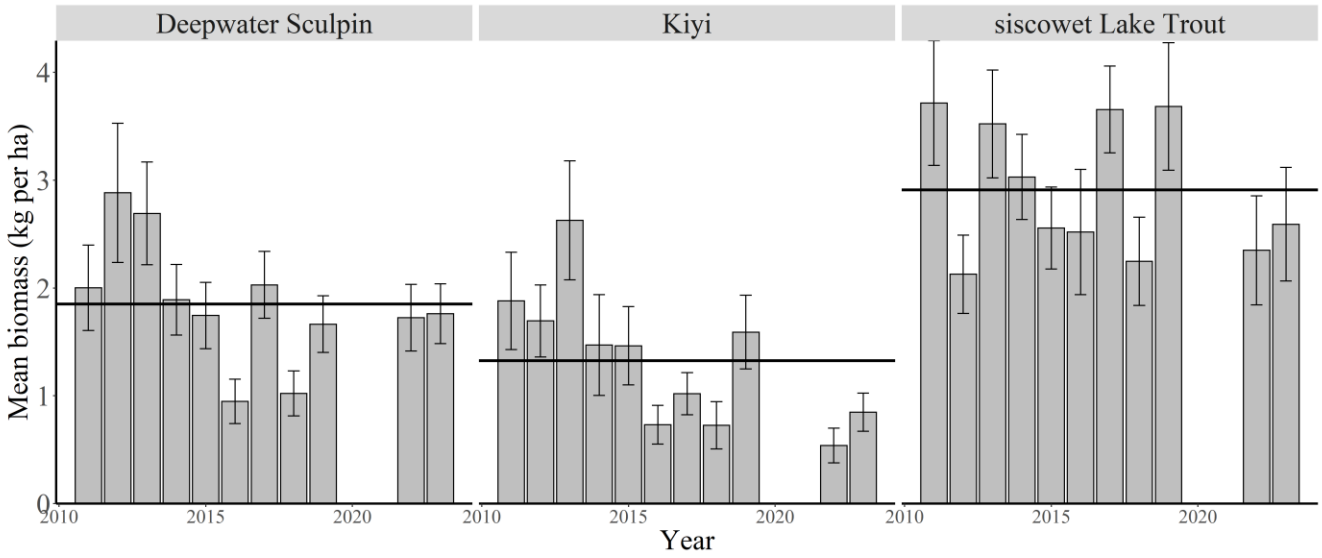

Figure 8. Annual offshore biomass estimates (mean lakewide kg per ha ± standard error) for Deepwater Sculpin, Kiyi and siscowet Lake Trout in USA and Canada waters of Lake Superior from 2011-2023. Offshore locations were 80-308 m deep. Annual offshore sampling locations were not sampled in 2020 and 2021 due to COVID-related travel restrictions. Scientific names are presented in Table 1.

Surface trawl fish collections

A total of 4,369 larval *Coregonus* individuals were collected in June-July 2023. This was the fewest *Coregonus* larvae collected in a whole lake survey since the survey began in 2014 (range 4,369-21,197 fish). In 2023, nearshore mean larval *Coregonus* densities were 416 per ha in June and offshore densities were 26 per ha in July (Figure 9). Average 2023 larval *Coregonus* densities were the second lowest estimate in June (range 336-1,027 per ha) and the lowest estimate in July (range 26-501 per ha) as compared to all previous years (2014-2023). Low larval *Coregonus* populations in 2023 were a stark contrast to that observed in

2022 when survival through July was the highest for the period-of-record for this survey which in turn led to high survival of *Coregonus* species to age-1.

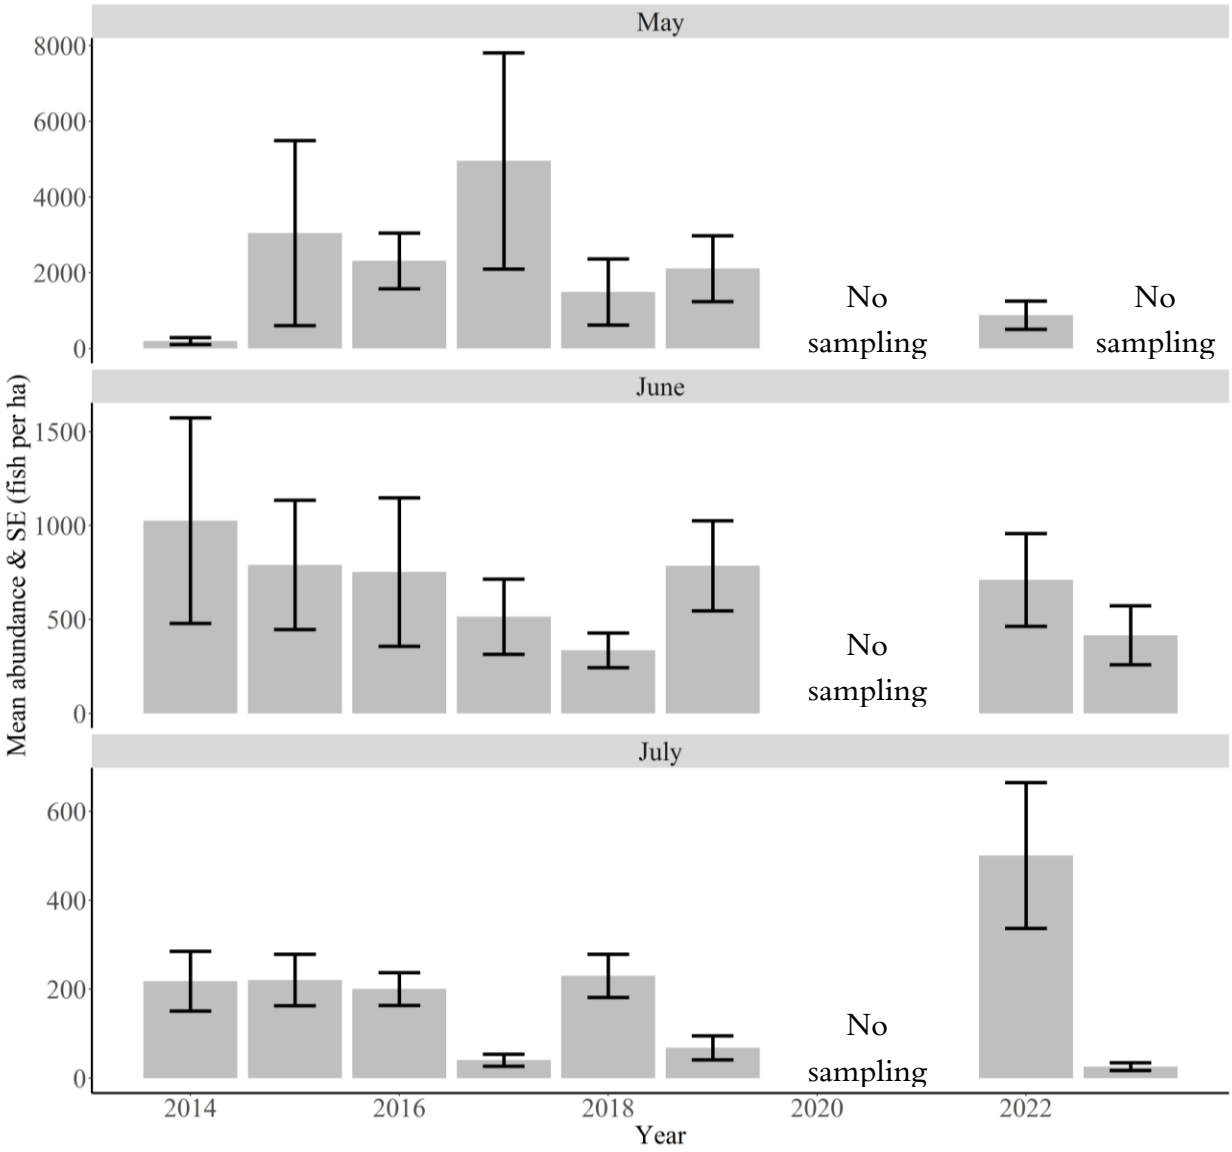

Figure 9. Monthly mean larval Coregonus abundance estimates (fish per ha ± standard error) for May, June, and July from USA and Canada waters of Lake Superior from 2014-2023, sans 2020 and 2021, due to COVID-related travel restrictions. Nearshore sampling locations were sampled in June and were 17-140 m deep. Offshore locations sampled in July and were 80-308 m deep. In 2023, sampling did not occur in May due to a vessel crew shortage. Sampling locations were from the nearshore survey in May and June and from the offshore survey in July. Sampling locations are shown in Figure 1. Note different y-axis scales.

Summary

Over the 46-year history of the U.S. Geological Survey's Lake Superior nearshore fish community surveys, total estimated biomass of benthic and demersal fish has reflected the survival of Bloater, Cisco, and Lake Whitefish populations to age-1+. In 2023, record survival of the Bloater and Cisco 2022 year-class to age-1 led to the second highest nearshore prey fish biomass estimate for the nearshore survey's period-of-record (1978-2023). If the future can be predicted by past large ciscoe year-class events, the unprecedented survival of the 2022 ciscoe (Bloater, Cisco, and Kiyi, *sensu* Eshenroder et al. 2016) year-class will influence the Lake Superior ecosystem for the next 10 to 20-years.

The combination of our near- and offshore bottom and surface trawl surveys provide a lakewide picture of the status and trends of the Lake Superior fish community susceptible to these trawls, particularly with respect to describing larval and age-1 *Coregonus* species population metrics and offshore Deepwater Sculpin, Kiyi, and siscowet Lake Trout populations. Our plan is to continue these surveys into the future and adapt them as needed to address emerging issues.

Table 2. *Annual lakewide bottom trawl biomass (kg per ha) estimates for all species and for a few common prey fishes collected in the nearshore bottom trawl survey in USA and Canada waters of Lake Superior, 1978-2023. Nearshore sampling locations were 17-140 m deep. Sculpin includes Slimy, Spoonhead, and Deepwater Sculpin. Mean and median total biomass includes all species. Other species includes Ninespine Stickleback, Trout-perch, Kiyi, Shortjaw Cisco, Pygmy Whitefish, Round Whitefish, Longnose Sucker, and lean, siscowet, and hatchery Lake Trout. Scientific names are presented in Table 1. Zero fish locations are the number of locations where no fish were collected.*

Table 3. Age-1 Bloater, Cisco, Lake Whitefish, and Rainbow Smelt densities (fish per ha) in an annually conducted nearshore bottom trawl survey and age-1 Kiyi densities from an annual offshore survey in USA and Canada waters of Lake Superior. Nearshore sampling locations were 17-140 m deep and offshore locations were 80-308 m deep. Age-1 fish were defined by species-specific lengths: Cisco <140 mm, Bloater <130 mm, Kiyi <130 mm, Lake Whitefish <160 mm, and Rainbow Smelt <100 mm. Scientific names are presented in Table 1.

Sampling year	Year class	Sampling locations nearshore / offshore	Bloater	Cisco	Kiyi	Lake Whitefish	Rainbow Smelt
1978	1977	43 /	0.72	0.02		2.60	83.85

Status and Trends in the Lake Superior Fish Community, 2023

Mark R. Vinson, Lori M. Evrard, Owen T. Gorman, Sydney B. Phillips, and Daniel L. Yule
U.S. Geological Survey Great Lakes Science Center Lake Superior Biological Station
2800 Lakeshore Drive East, Ashland, Wisconsin 54806 (mvinson@usgs.gov)

Appendix B. Comparison of annual Lake Superior total fish community biomass (kg per ha) and age-1 abundance estimates for Bloater (*Coregonus hoyi*), Cisco (*C. artedi*), Lake Whitefish (*C. clupeaformis*), and Rainbow Smelt (*Osmerus mordax*) from the United States (USA) and Canada with and without roller-trawl locations. Nearshore sampling locations were 17-140 m deep. Any use of trade, product, or firm names is for descriptive purposes only and does not imply endorsement by the U.S. Government.

	Locations sampled		Total biomass, kg per ha		age-1 Bloater per ha		age-1 Cisco per ha		age-1 Lake Whitefish per ha		age-1 Rainbow Smelt per ha	
Year	All trawls	No roller trawls	All trawls	No roller trawls	All trawls	No roller trawls	All trawls	No roller trawls	All trawls	No roller trawls	All trawls	No roller trawls

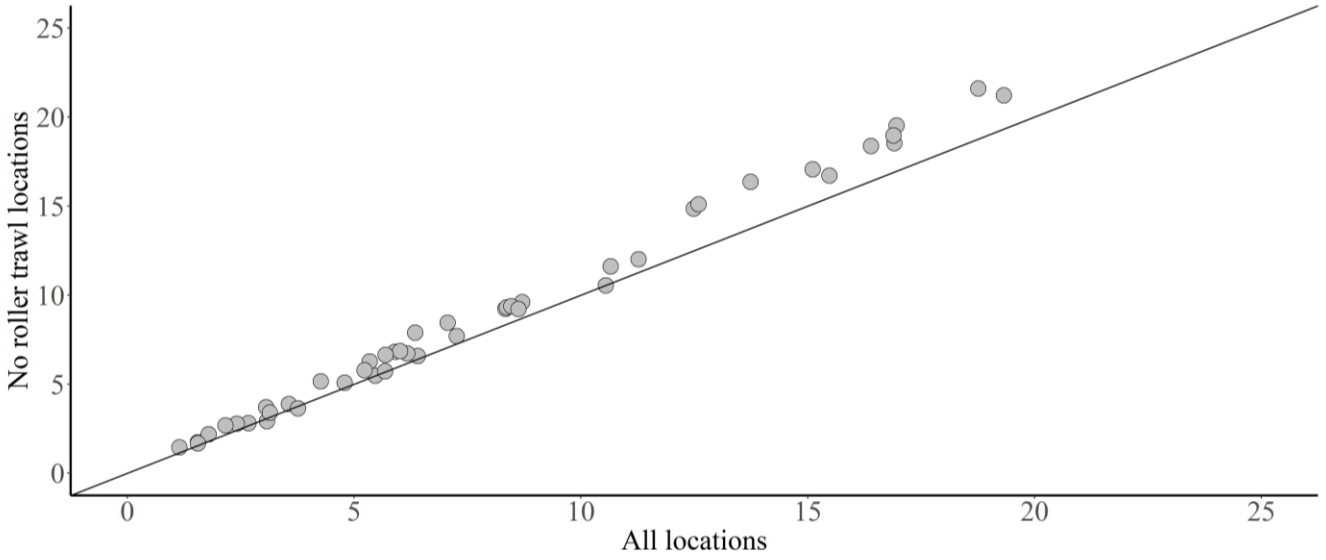

Figure B1. Annual mean total fish biomass estimates from bottom trawls for all sampling locations and for non-roller trawl locations from 1978-2023 in nearshore USA waters of Lake Superior. From 1978-1988 and in 2021 only USA waters were sampled. The number of locations sampled in each year are presented in Appendix B. The diagonal line indicates equality between the two data sets.

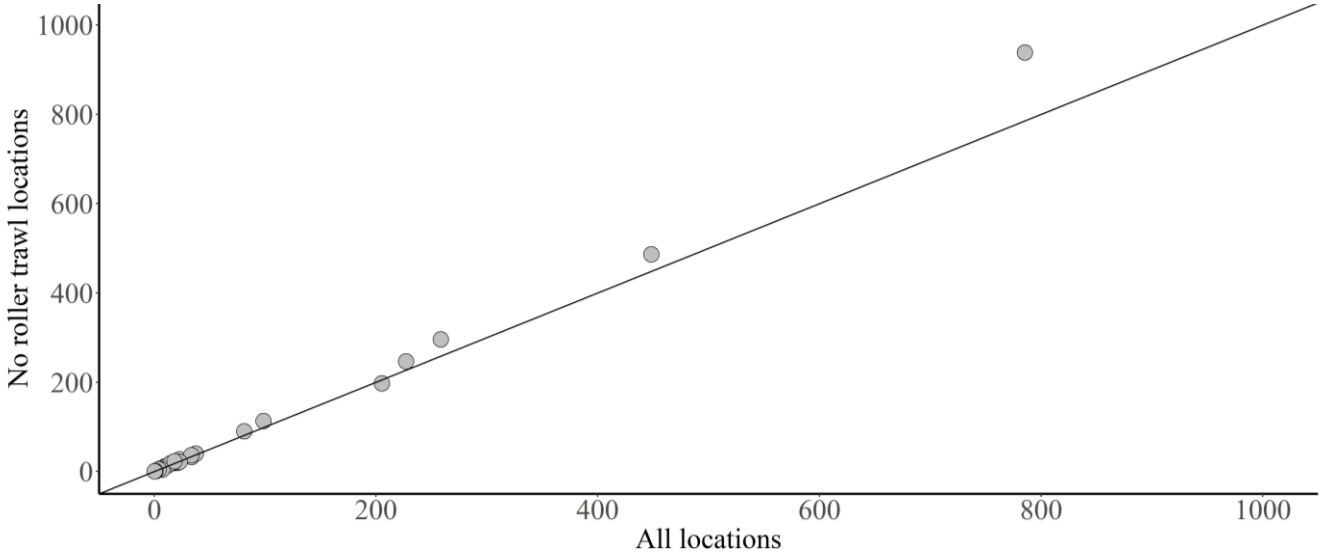

Figure B2. Annual mean age-1 Cisco (Coregonus artedi) abundance estimates (age1- Cisco per ha) from bottom trawls for all sampling locations and for non-roller trawl locations from 1978-2023 in nearshore USA waters of Lake Superior. From 1978-1988 and in 2021 only USA waters were sampled. The number of locations sampled in each year are presented in Appendix B. The diagonal line indicates equality between the two data sets.
